

Developmental Delay

About Sound Therapy:

Sound-based therapy involves the use of sound vibration that impacts the body using special equipment, programs, modified music, and/or specific tones/beats, the need for which is identified with appropriate testing.

About Developmental Delay:

Developmental Delay is a term used when a child does not reach the expected developmental milestones such as speaking, crawling or walking, at the usual time. Developmental Delay may or may not indicate a long term developmental disorder as most children recover from the delay. (access.autistics.org/resources/glossary/main.html)

Therapies Offered:

AIT, Listening Training Programs, Tomatis®, Fast ForWord™, Interactive Metronome™, BioAcoustics™, and other home programs. Therapies are only suggested after completing the Diagnostic Evaluation for Therapy Protocol (DETP®) which determines if any sound-based therapy is appropriate and when it is, in the correct order. We utilize *The Davis Model of Sound Intervention*®.

Sound-based therapies are not medical treatments. They do not cure or treat medical disease conditions. They work on supporting change in auditory processing, learning, development, and wellness. The work of The Davis Center is no substitute for a medical diagnosis and treatment.
